

Forest Health Protection Pacific Southwest Region

Date: March 2, 2017
File Code: 3420

To: Forest Supervisors (Eldorado, Inyo, Lassen, Modoc, Plumas, Sierra, Stanislaus, Sequoia and Tahoe National Forests and the Lake Tahoe Basin Management Unit), Park Superintendents (Sequoia Kings Canyon and Yosemite National Parks), Field Managers (Bureau of Land Management, Eagle Lake and Alturas Field Offices), and Deputy Director (CAL FIRE Resource Management)

Subject: Douglas-fir Tussock Moth: Results of 2016 Pheromone Detection Survey (FHP Report NE17-03)

The following are the results of the 2016 cooperative Douglas-fir tussock moth (DFTM) pheromone detection survey. Participation in this effort includes the US Forest Service, CAL FIRE, Bureau of Land Management and the National Park Service.

Report Summary

- Douglas-fir tussock moth trap catches were extremely low in all survey areas.
- No defoliation was reported anywhere in 2016.
- Defoliated white fir have recovered in nearly all areas affected by the 2013/2014 outbreak on the Plumas and Lassen National Forests.
- Information on DFTM biology and management is included in Appendix A.

Results

Traps were installed in 141 plots this year with 84% reporting. No plots averaged > 25 male moths per trap (Table 1). A greater than 25 per trap average is considered high and follow up egg mass and/or larval density surveys are conducted on these plots to determine the potential for defoliation in the coming year.

Effects of recent outbreak

Nearly all areas affected by the recent outbreak are seeing a full recovery of defoliated white fir (Figure 1). Even the most affected areas are showing partial crown recovery with only scattered top-kill or whole tree mortality.

Figure 1. Left Pictures = white fir defoliated by Douglas-fir tussock moth in 2014, Plumas National Forest
Right Pictures = same white fir in 2016 showing recovery

2017 Survey

Forest Health Protection and/or CAL FIRE Pest Management staff will conduct additional monitoring and report any defoliation to the appropriate land managers. Field going personnel are urged to continue to check for evidence of feeding and defoliation on white fir this coming summer and fall and report any findings to your local forest health contacts (Appendix B).

Trapping materials have been ordered for the detection survey plots for 2017 and will be distributed to cooperators in June or July. Updates on population monitoring will be distributed to land managers as needed.

Forest Health Protection appreciates the continued cooperation from all agencies in this ongoing west-wide survey effort and especially thanks the following DFTM Detection Survey cooperators:

Tom Smith, CAL FIRE, Davis
Jim Kral, CAL FIRE, Mountain Home DSF
David Shy, CAL FIRE, Tulare
Frank Spandler, CALFIRE Tulare
Tom Warner, NPS, Sequoia Kings Canyon
Brian Mattos, NPS, Yosemite
Cliff Motheral, BLM, Susanville
Cathy Carlock, Modoc NF
Barbara Bryan, Modoc NF
Sandy Tiffin, Lassen NF
Sandra Osman, Lassen NF
Paul White, Lassen NF
Ryan Tompkins, Plumas NF
Charlie Hiles, Tahoe NF
Kelly Bowdoin, Tahoe NF
Jerald Griffin, Tahoe NF

James Ingram, Eldorado NF
Jeff Griffin, Eldorado NF
Bob Carroll, Eldorado NF
Dana Walsh, Eldorado NF
Melanie Harnage, Eldorado NF
Kathy Stillwell, Stanislaus NF
David Vosti, Stanislaus NF

Appendix A: Douglas-fir Tussock Moth Biology and Management

The Douglas-fir tussock moth (DFTM), *Orgyia pseudotsugata*, is an important defoliator of white fir in California. Outbreaks of the native insect occur somewhere in the state about every 10 years. These outbreaks arise abruptly, but generally subside within one to two years. White fir is the primary host, but other tree species may be defoliated during outbreaks. Defoliation by DFTM may weaken, kill, or top-kill trees. Heavily defoliated trees may experience reduced growth for several years post outbreak and be more susceptible to attacks by bark beetles. Ninety percent of mortality occurs in trees that are $\geq 90\%$ defoliated, while trees with $\leq 50\%$ defoliation rarely die. Top-kill follows a similar trend.

Defoliation first appears in late spring. Larvae from newly-hatched eggs feed on current year's foliage, causing it to shrivel and turn brown. Older larvae may feed on both current and old foliage, although current needles are preferred. Defoliation occurs first in the tops of the trees and the outermost portions of the branches, and then in the lower crown and farther back on the branches.

The adult male is a gray-brown to black-brown moth with feathery antennae and a wingspread of 1 to 1 1/4 inches. The forewings are gray brown and have two distinct, irregular dark bars and two vague whitish spots. The hindwings are a contrasting brown. The female has tiny rudimentary wings, small threadlike antennae, and a large abdomen. Young larvae are 1/8 to 1/4 inch long and have long, fine body hairs which later develop into tufts. Mature larvae are up to 1 1/4 inches long and very colorful. Two long, dark tufts or pencils of hair similar to horns are located right behind the head.

Four dense, buff colored tussocks are located forward along the middle of the back. The rest of the body except for the legs and head is covered with short hairs radiating from red, button like centers (see photo).

Douglas-fir tussock moth larvae (differences in color and size are due to stage of development).

The DFTM produces one generation per year. Females mate soon after they emerge from their pupal cocoon. Eggs hatch in early June, coincident with bud break and shoot elongation of host trees. The larvae pass through four to six instars and pupate toward the end of the July. The pupal stage lasts from 10-18 days depending on temperature.

Natural controls keep DFTM populations low most of the time. There is some indication that fir growing on pine sites and fir stands located on warm, dry sites are most susceptible to damage. In these forest situations, silvicultural treatments that reduce the number of susceptible hosts and decrease the multi-storied characteristics of host stands are recommended to prevent outbreaks.

When population levels are high enough to cause unacceptable damage, methods of direct control are available. The viral insecticide, TM-Biocontrol-1, is currently registered in California for use against DFTM. Other registered insecticides are also effective against DFTM including broad spectrum insecticides and more targeted growth regulators and microbial insecticides. Applications of insecticides are made aerially over large areas or with ground based equipment on individual trees. Where DFTM-caused defoliation is expected in high value areas, such as recreation areas or on individual high-value trees, pesticide use may be warranted to minimize tree mortality and reduce public exposure to the insect.

Public Health Concerns

The hairs on the caterpillars as well as their egg masses and cocoons may cause allergic reactions in some people. Itching is the most common complaint, but adverse health effects can include rashes (with welts or blisters), watery eyes, runny nose, cough and, less commonly, shortness of breath, wheezing, and chest tightness. Hot weather and perspiration increase the severity of symptoms, and people with a history of allergies may be more susceptible to “tussockosis.” Accidental disturbance or handling of old larval skins and spent cocoons, deposited under leaf litter, bark, wood piles, timber, or any other material that caterpillars have touched, can result in irritation. Irritation intensity depends upon the amount of contact with the caterpillar and the sensitivity of the person. The effects may be cumulative, with successive exposures resulting in elevated symptoms. During a 1998 outbreak at Grant Grove in Kings Canyon National Park, approximately 100 people sought medical attention or advice, resulting in a temporary closure of the area for health and safety reasons.
